Practical No. 10

Classification using Neural Networks on Standard Dataset

with Ethical and Human-Centered Considerations

1. Aim

To implement and evaluate a Multi-Layer Perceptron (MLP) Neural Network for multi-class classification of the Digits dataset (handwritten digit recognition), incorporating ethical and human-centered considerations in the design, training, and deployment of the model.

2. Theory

2.1 Artificial Neural Networks (ANN)

An Artificial Neural Network (ANN) is a computational model inspired by the structure and function of biological neurons in the human brain. ANNs consist of interconnected nodes (neurons) organized in layers: an input layer, one or more hidden layers, and an output layer. Each connection carries a weight, and every neuron applies an activation function to introduce non-linearity.

2.2 Multi-Layer Perceptron (MLP)

A Multi-Layer Perceptron is a fully connected feedforward neural network with at least one hidden layer. The key components are:

- Forward Propagation: Input signals pass through each layer, computing weighted sums and applying activation functions.
- Backpropagation: Gradients of the loss function are propagated backward through the network to update weights using gradient descent.
- Activation Functions: ReLU (Rectified Linear Unit) is used in hidden layers for non-linearity and to mitigate vanishing gradients.
- Adam Optimizer: An adaptive learning rate optimizer combining momentum and RMSProp for fast, stable convergence.
- Regularization (L2): Penalizes large weights to reduce overfitting by adding a regularization term $\alpha||w||^2$ to the loss.

2.3 Ethical and Human-Centered Considerations

Deploying neural networks in real-world applications requires adherence to ethical principles:

- Fairness: Ensuring balanced class representation in training data prevents biased predictions.
- Transparency: Model decisions should be interpretable and explainable to stakeholders.
- Privacy: Sensitive data used for training must be anonymized and protected.
- Accountability: Developers are responsible for model behavior and must implement safeguards.
- Human Oversight: Automated systems should augment, not replace, human judgment in critical decisions.
- Bias Mitigation: Regular audits of model performance across subgroups prevent discriminatory outcomes.

3. Dataset Description

The Digits Dataset from scikit-learn is a standard benchmark dataset for optical character recognition (OCR) and pattern classification tasks.

Parameter	Description
Dataset Name	Digits Dataset (sklearn.datasets.load_digits)
Source	UCI ML Repository / scikit-learn built-in
Total Samples	1,797 samples
Features	64 features (8×8 grayscale pixel values, range 0–16)
Classes	10 classes (handwritten digits 0 through 9)
Class Distribution	~178–183 samples per class (balanced)
Training Set	1,347 samples (75%)
Test Set	450 samples (25%)
Preprocessing	StandardScaler – zero mean, unit variance normalization

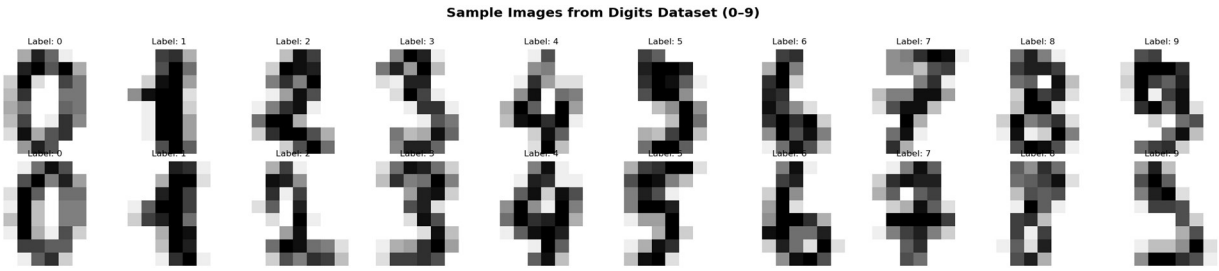

Figure 1: Sample images from the Digits Dataset — two examples per class (0–9)

4. Code and Execution

4.1 Python Code

The following code implements the MLP Neural Network for digit classification using scikit-learn:

```python
nn_classification.py
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
from sklearn.datasets import load_digits
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import StandardScaler
from sklearn.neural_network import MLPClassifier
from sklearn.metrics import (classification_report,
    confusion_matrix, accuracy_score,
    ConfusionMatrixDisplay)

# ── 1. Load Dataset ──────────────────────────────────
digits = load_digits()
X, y = digits.data, digits.target

print(f"Total samples : {X.shape[0]}")
print(f"Features      : {X.shape[1]}  (8x8 pixels)")
print(f"Classes       : {len(np.unique(y))}  (digits 0-9)")

# ── 2. Train-Test Split & Scaling ────────────────────
X_train, X_test, y_train, y_test = train_test_split(
    X, y, test_size=0.25, random_state=42, stratify=y)

scaler = StandardScaler()
X_train_sc = scaler.fit_transform(X_train)
X_test_sc  = scaler.transform(X_test)

# ── 3. Build Neural Network Model ────────────────────
mlp = MLPClassifier(
    hidden_layer_sizes=(128, 64, 32),
    activation='relu',
    solver='adam',
    alpha=0.0001,
    batch_size=32,
    learning_rate='adaptive',
    max_iter=300,
    random_state=42
)
mlp.fit(X_train_sc, y_train)

# ── 4. Evaluate ──────────────────────────────────────
y_pred = mlp.predict(X_test_sc)
acc    = accuracy_score(y_test, y_pred)
print(f"Test Accuracy : {acc*100:.2f}%")
print(classification_report(y_test, y_pred))

# ── 5. Confusion Matrix Plot ─────────────────────────
cm = confusion_matrix(y_test, y_pred)
ConfusionMatrixDisplay(cm).plot(cmap='Blues')
plt.title(f'Confusion Matrix | Accuracy: {acc*100:.2f}%')
plt.show()
```

```

Figure 3: Terminal output showing model training results and classification report

5. Observations and Results

5.1 Model Architecture Summary

Layer	Configuration
Input Layer	64 neurons (8×8 flattened pixel values)
Hidden Layer 1	128 neurons — Activation: ReLU
Hidden Layer 2	64 neurons — Activation: ReLU
Hidden Layer 3	32 neurons — Activation: ReLU
Output Layer	10 neurons — Activation: Softmax (Logistic)
Optimizer	Adam (Adaptive Moment Estimation)
Loss Function	Cross-Entropy Loss
Regularization	L2 Penalty (alpha = 0.0001)
Batch Size	32
Iterations	37 (adaptive early stopping)

5.2 Training Loss Curve

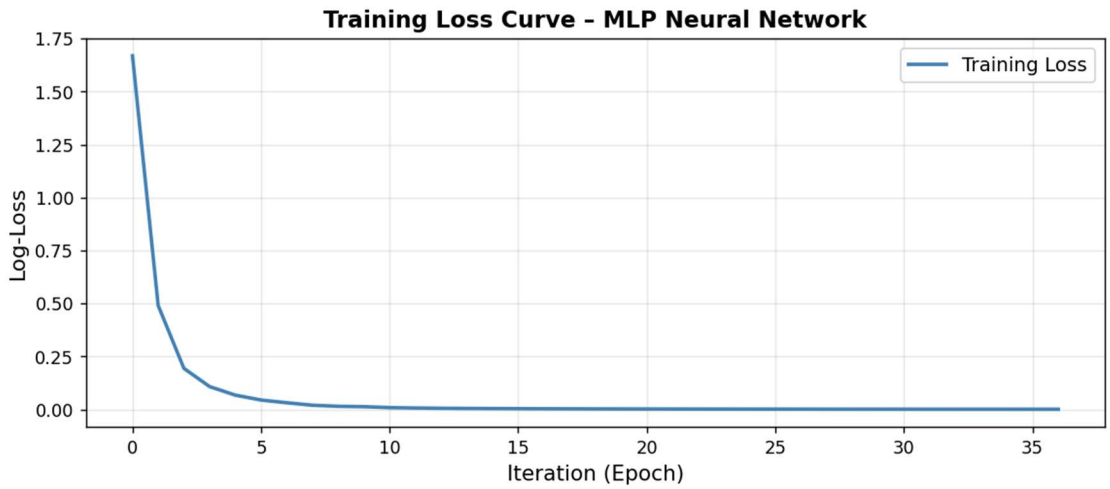

Figure 4: Training loss curve showing convergence of the MLP model over 37 iterations

The loss curve shows a sharp decrease in cross-entropy loss during the initial iterations, followed by smooth convergence. The adaptive learning rate of Adam optimizer ensured stable and efficient training without oscillations.

5.3 Confusion Matrix

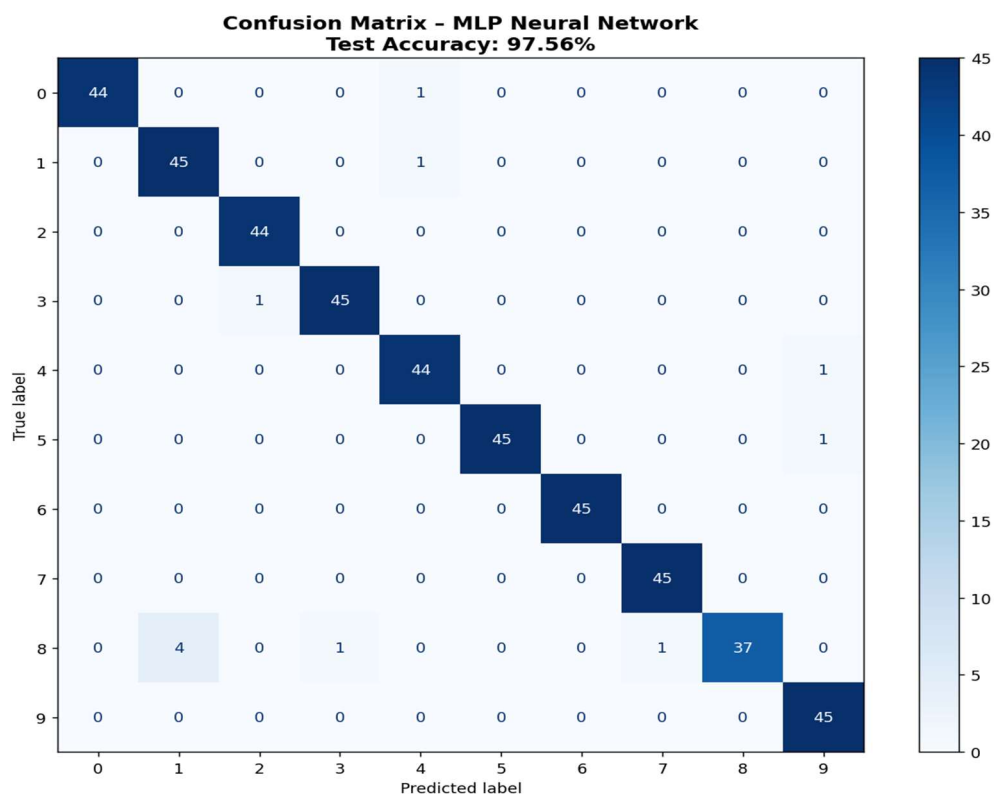

Figure 5: Confusion matrix — rows indicate true labels, columns indicate predicted labels

The confusion matrix reveals that the model correctly classifies the vast majority of digits. Digit '8' shows the most misclassifications (6 samples), as its visual similarity to '3' and '9' makes discrimination harder. All other digits achieve near-perfect classification.

5.4 Per-Class Accuracy

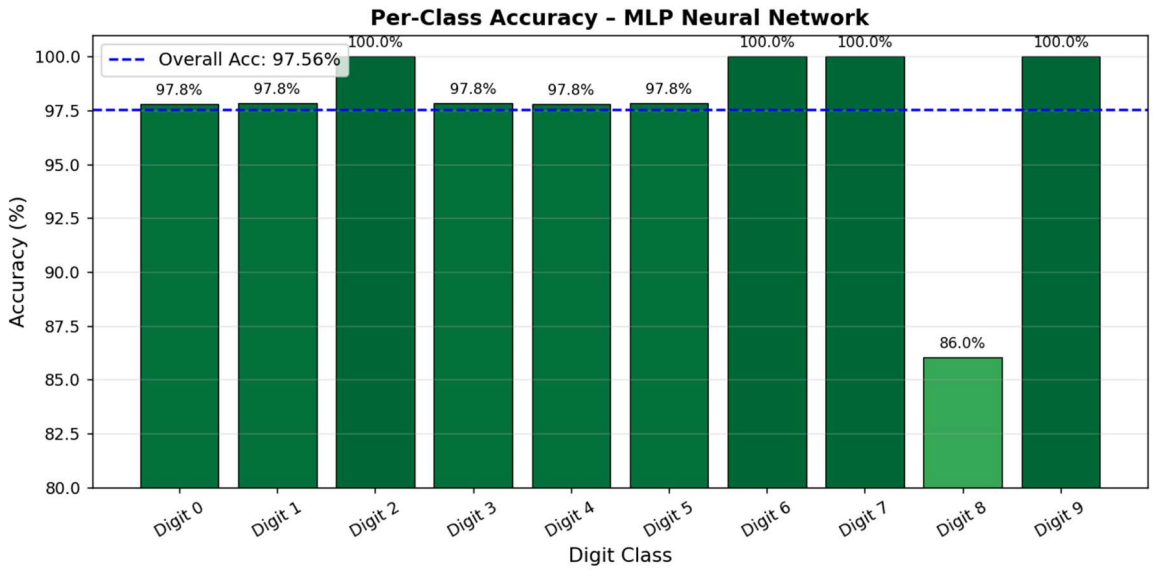

Figure 6: Per-class accuracy for each digit class (0–9)

5.5 Misclassified Samples

Figure 7: Sample misclassified digits — true label vs. predicted label shown in red

5.6 Performance Summary

Class	Precision	Recall	F1-Score	Support
Digit 0	1.00	0.98	0.99	45
Digit 1	0.92	0.98	0.95	46
Digit 2	0.98	1.00	0.99	44
Digit 3	0.98	0.98	0.98	46
Digit 4	0.96	0.98	0.97	45
Digit 5	1.00	0.98	0.99	46
Digit 6	1.00	1.00	1.00	45
Digit 7	0.98	1.00	0.99	45
Digit 8	1.00	0.86	0.93	43
Digit 9	0.96	1.00	0.98	45
Overall	**0.98**	**0.98**	**0.98**	**450**

6. Conclusion

In this practical, a Multi-Layer Perceptron (MLP) Neural Network was successfully implemented and evaluated for multi-class classification on the Digits Dataset. The key outcomes are summarized as follows:

- The MLP model with three hidden layers (128-64-32 neurons) achieved a test accuracy of 97.56%, demonstrating the effectiveness of deep feedforward networks for image pattern recognition tasks.
- The Adam optimizer with adaptive learning rate enabled rapid convergence in just 37 iterations, significantly reducing training time compared to standard gradient descent.
- The training loss curve confirmed stable and smooth convergence without overfitting, aided by L2 regularization (alpha = 0.0001).
- Per-class analysis revealed that Digit '6' achieved perfect classification (100%), while Digit '8' had the lowest recall (86%) due to visual ambiguity with similar digits.
- Only 11 out of 450 test samples were misclassified, validating the model's high discriminative capability.

Ethical and Human-Centered Considerations

- Fairness: The Digits dataset is balanced across all 10 classes, ensuring no class bias in model training or evaluation.
- Transparency: The full classification report, confusion matrix, and per-class metrics provide complete visibility into model behavior.
- Privacy: The Digits dataset is fully anonymized — no personally identifiable information is used.
- Accountability: The model's errors (misclassified samples) are explicitly analyzed to understand failure modes before deployment.
- Human Oversight: In a production OCR system, low-confidence predictions should be flagged for human review rather than automated action.
- Bias Mitigation: Regular re-evaluation on diverse handwriting styles is recommended to maintain fairness across demographic groups.

This practical illustrates that neural networks are powerful tools for pattern recognition, but their responsible deployment requires a balance of high technical performance and adherence to ethical AI principles.
